

ABSTRACT

[00022] An undersea hydraulic coupling is disclosed having tails on both the male and female members to allow insertion through and attachment to manifold plates. The tails on the hydraulic coupling members are provided with substantially rigid positioning members to allow the coupling members to be held in a nominal position with respect to the manifold plate, thereby preventing galling when the coupling members are mated, and further preventing unnecessary crimping or pressure weakened points at the connection of the tail to hydraulic lines.
